Description

FIELD OF THE INVENTION

This invention is in the field of mammalian therapeutics and relates to compounds for treatment of mammalian diseases such as inflammation, cardiovascular disorders, asthma and other diseases. Of particular interest is a class of 5-substituted imidazo [4,5-c] pyridines useful for treatment of cardiovascular and immuno-inflammatory related disorders mediated by platelet activating factor (PAF).

BACKGROUND OF THE INVENTION

Platelet-activating factor (PAF) has been associated with various biological activities and pathways, thus making it an important mediator responsible for a variety of physiological processes including, but not limited to, activation and aggregation of platelets, smooth muscle contraction, pathogenesis of immune complex deposition, inflammation, and respiratory, cardiovascular and intravascular alterations. These physiological processes are associated with a large group of diseases, such as, for example, cardiovascular disorders, asthma, lung edema, endotoxin shock, adult respiratory distress syndrome and inflammatory diseases.

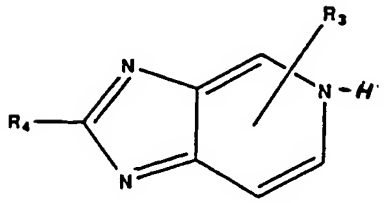
All of these salts may be prepared by conventional means by reacting, for example, the appropriate acid with the corresponding compound of Formula I.

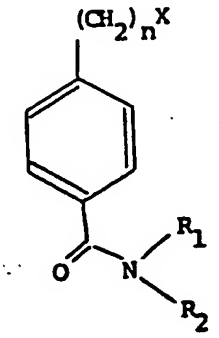
The compounds of formula (I) may be prepared in accordance with the following procedures.

Imidazopyridine which is represented by the following formula

II



wherein R_3 and R_4 are defined as before is reacted with a haloalkylbenzamide which is represented by the following formula



III

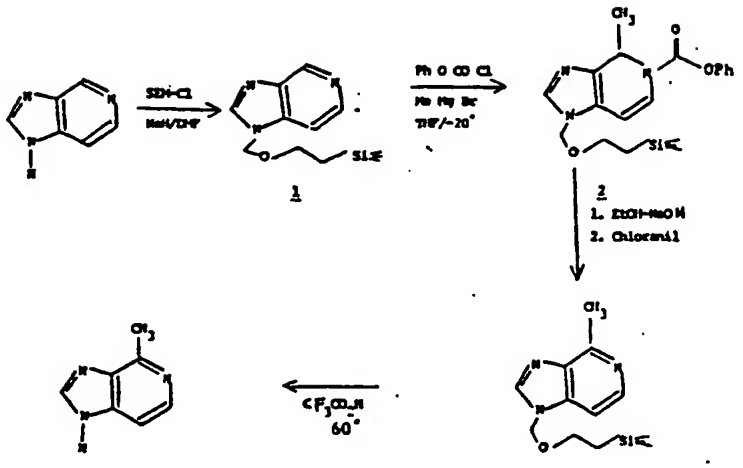
wherein R_1 and R_2 and n are defined as before and X is chloro, bromo, or methanesulfonyloxy to give the compounds of formula I. It is understood that the haloalkylbenzamide can also be substituted once or more by halogen, alkyl of 1 to 6 carbon atoms; alkoxy wherein the alkyl is 1 to 6 carbon atoms; thioalkyl wherein the alkyl is 1 to 6 carbon atoms; alkoxyalkyl wherein the alkyl is 1 to 6 carbon atoms; hydroxyalkyl wherein the alkyl is 1 to 6 carbon atoms; alkylthioalkyl wherein the alkyl is 1 to 6 carbon atoms; cyano; mercaptoalkyl wherein the alkyl is 1 to 6 carbon atoms; hydroxy; amino; alkylamino wherein the alkyl group is 1 to 6 carbon atoms and dialkylamino wherein the alkyl group are each 1 to 6 carbon atoms.

After heating overnight the reaction solvent is removed in vacuo and the residue diluted with water and basified with ammonium hydroxide. The aqueous solution is extracted with chloroform and the combined organic extracts are backwashed with saturated aqueous sodium chloride solution. The organic solution is dried over sodium sulfate or magnesium sulfate, the drying agent filtered and the filtrate concentrated in vacuo to give the crude product. Purification is effected by chromatography on silica gel using mixtures of chloroform, ethanol and ammonium hydroxide.

A preferred work up for the above-described procedure is to cool the reaction solution which had been heated overnight to room temperature and remove the solvent under reduced pressure at <45 °C. The residue obtained is triturated with excess of dry ether and filtered. The crude product is purified by chromatography.

Preparation of Intermediates

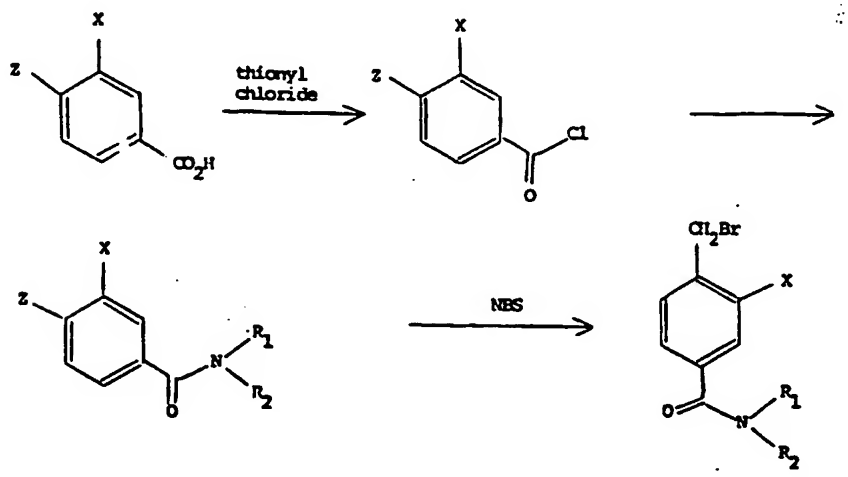
Scheme A



The imidazo [4,5-c]pyridine wherein R_3 is 4-methyl is prepared according to the scheme above starting with the imidazopyridine of Formula II. Position 1 of this compound is protected by reaction with a 2-(trialkylsilyl)ethoxymethyl chloride and a base such as sodium hydride or potassium hydride in a polar aprotic solvent such as dimethylformamide. This reaction is carried out at room temperature. A specific example of such a protecting reagent is 2-(trimethylsilyl)ethoxymethyl chloride. The protected imidazopyridine is reacted with phenyl chloroformate and methylmagnesium bromide in an ether solvent such as tetrahydrofuran at about -20 °C. The methylated product bearing phenoxycarbonyl at position 5 is treated with a base, such as alcoholic sodium hydroxide, at reflux for 24 hr. The product is oxidized with, for example, chloranil, and the 2-(trimethylsilyl)ethoxymethyl group is removed by treatment with a suitable acid. An example of such an acid would be trifluoroacetic acid. Preparation of the unsubstituted imidazo [4,5-c] pyridine is described in US-A-4,804,658.

The haloalkyl benzamides are prepared according to the following reaction scheme

Scheme B



wherein R_1 and R_2 are defined as before; Z is CH_2Br or H; X is fluoro, OMe or methyl

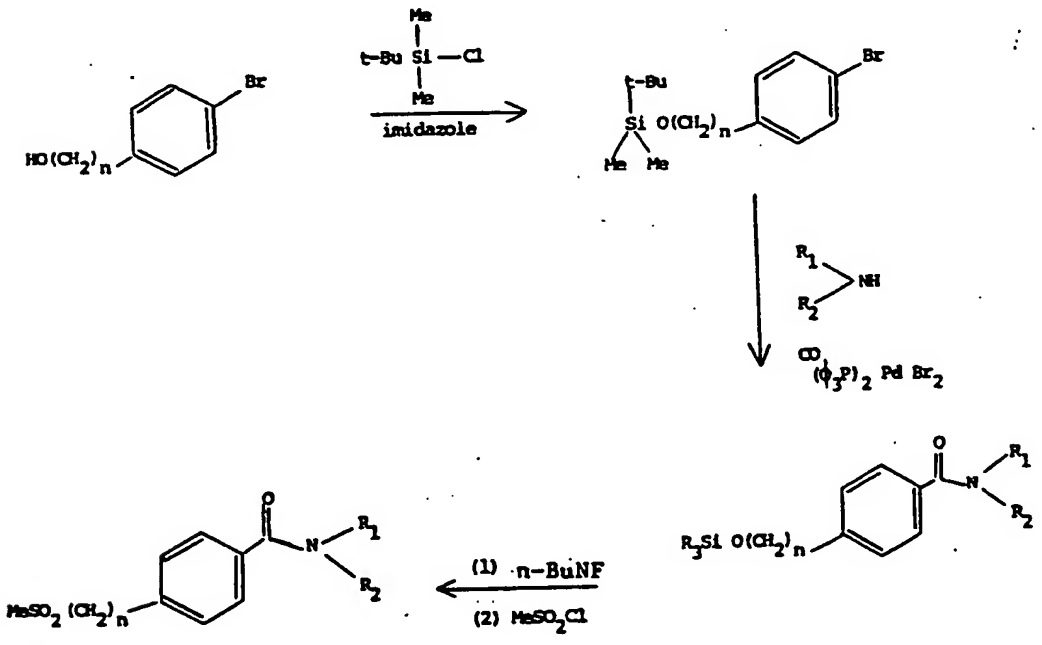
Thus according to the above scheme the acid chlorides were prepared from the corresponding carboxylic acids by refluxing in thionyl chloride (2 molar excess) for two hours. Excess thionyl chloride was removed by azeotrope with toluene. The residual acid chloride was dissolved in THF and cooled to -10°C. A solution of two molar equivalents of the secondary amine in the THF was added dropwise with stirring. When addition was completed, the reaction was allowed to warm to room temperature and stirred for 1-2 hours. The reaction was quenched with 1N HCL, diluted with H_2O and extracted three times with ethyl acetate. The combined organic layers were washed with saturated aqueous sodium bicarbonate solution, with water and with saturated aqueous sodium chloride and dried over sodium sulfate. The drying agent was filtered and the filtrate concentrated in vacuo to give a crude product that was chromatographed on silica gel using mixtures of ethyl acetate and hexane to give the purified amide.

When Z = CH_2Br and X = H, the above description is sufficient for the preparation of the compounds of Formula III. When Z = CH_3, and X = OMe or F, or when Z = H and X = CH_3 then compound of Formula VI must be treated with a halogenating agent such as N-bromo succinimide.

A stirred mixture of the purified amide and NBS (1:1 molar ratio) in carbon tetrachloride was irradiated with a sun lamp for 1-3 hours. A white precipitate was filtered and washed with a minimum amount of $CHCl_3$. The filtrate was washed with water and the aqueous layer, after basification with ammonium hydroxide, was extracted three times with chloroform. All organic layers were combined, washed three times with saturated aqueous sodium chloride solution and dried over sodium sulfate.

The drying agent was filtered and the filtrate concentrated in vacuo to give a crude product that was chromatographed on silica gel using mixtures of ethyl acetate and hexane to give the purified bromomethyl compound.

Scheme C



The benzamides wherein n = 2 or 3 can be prepared according to the scheme above starting with the appropriate hydroxyalkyl bromobenzene. The hydroxyl group was protected as a trialkylsilyl ether by reaction with a trialkylsilyl chloride and imidazole in a suitable solvent such as dimethylformamide. An example of such a protecting group would be the t-butyldimethylsilyl ether. The crude silyl ether was purified by chromatography on silica gel using mixtures of ethyl acetate and hexane. The aryl bromide was converted to the carboxamide according to the procedure of Schoenberg et al. [J. Org. Chem., 39, 3327-(1974]. Thus, the aryl bromide was reacted with carbon monoxide in the secondary amine as solvent using

bistriphenylphosphine palladium(II) dibromide as catalyst at about 100 °C for 8-26 hr. in a pressure vessel. The reaction vessel was vented, the reaction mixture triturated with ethyl ether and the washings filtered. The filtrate was washed with 10% aqueous HCl, water and brine. After drying over a suitable drying agent, such as magnesium sulfate, and filtering, the filtrate was concentrated and the residue chromatographed on silica gel using mixtures of ethyl acetate and hexane as eluent to give pure product. The silyl ether was removed by reaction with tetra-n-butylammonium fluoride and the alcohol was converted to a sulfonate ester by reaction with an alkyl or arylsulfonyl chloride. An example of such a sulfonate would be the methanesulfonate.

The secondary amines may be prepared by any number of methods known to those skilled in the art. See references

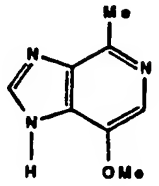
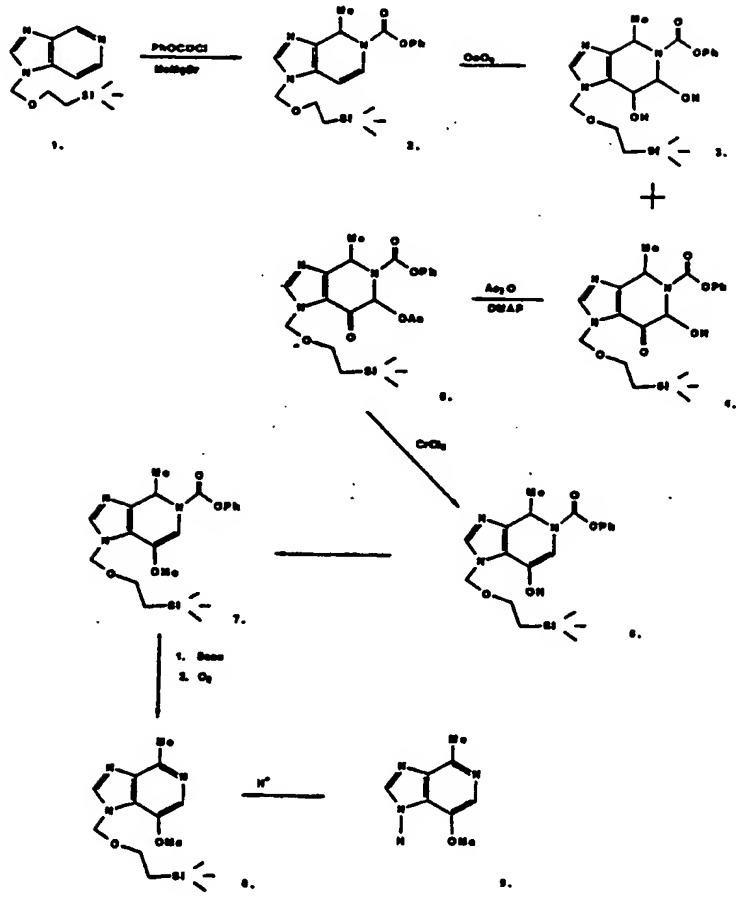
Preparation of 4-Methyl-7-methoxy-imidazopyridine



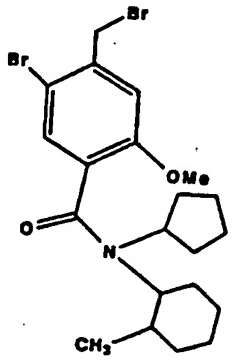
The above compound can be prepared by the following

Scheme D



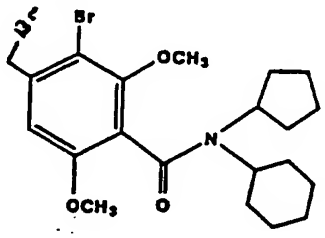
Thus the addition product 2 which is isolated on reacting 1 with phenyl chloroformate and methyl magnesium bromide is treated with osmium tetroxide in aqueous acetone containing N-methylmorpholine-N-oxide at room temperature for 24 hours to give the diol 3 and the hydroxyketone 4. The hydroxyketone 4 is acetylated (acetic anhydride, DMAP methylene chloride, room temperature, 24 hrs) and treated with $CrCl_2$ in acetone to give the deacetoxylated product 6. Product 6 is treated with NaH in DMF and then with iodomethane to give the methyl ether 7. Cleavage of carbamate and oxidation gives the N-1 protected 4-methyl-7-methoxy imidazopyridine product 8. Deprotection of product 8 gives the 4-methyl-7-methoxy-imidazopyridine.

Preparation of 2-Methoxy-4-bromomethyl-5-bromobenz(N-cyclopentyl,N-2-methylcyclohexyl)amide



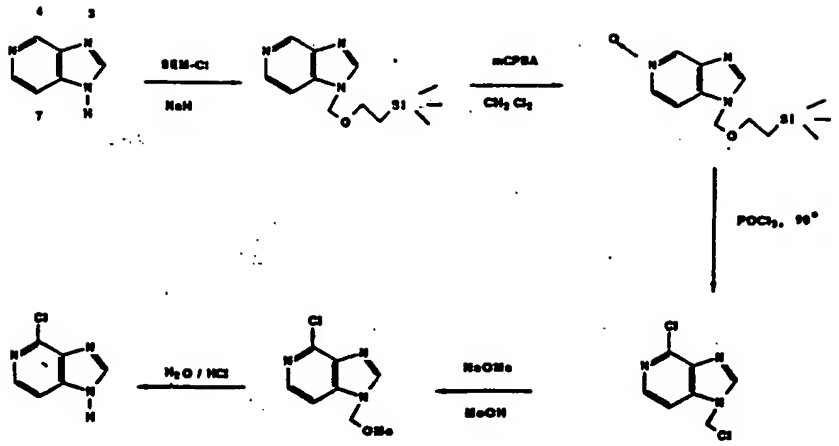
The above compound is prepared from 2-methoxy-4-methylbenz (N-cyclopentyl,N-2-methylcyclohexyl)-amide and N-bromo succinimide in carbon tetrachloride by irradiation with a sun lamp for 5 hours.

Preparation of 2,6-Dimethoxy-3 bromo-4-bromomethylbenz (N-cyclohexyl,N-cyclopentyl)amide



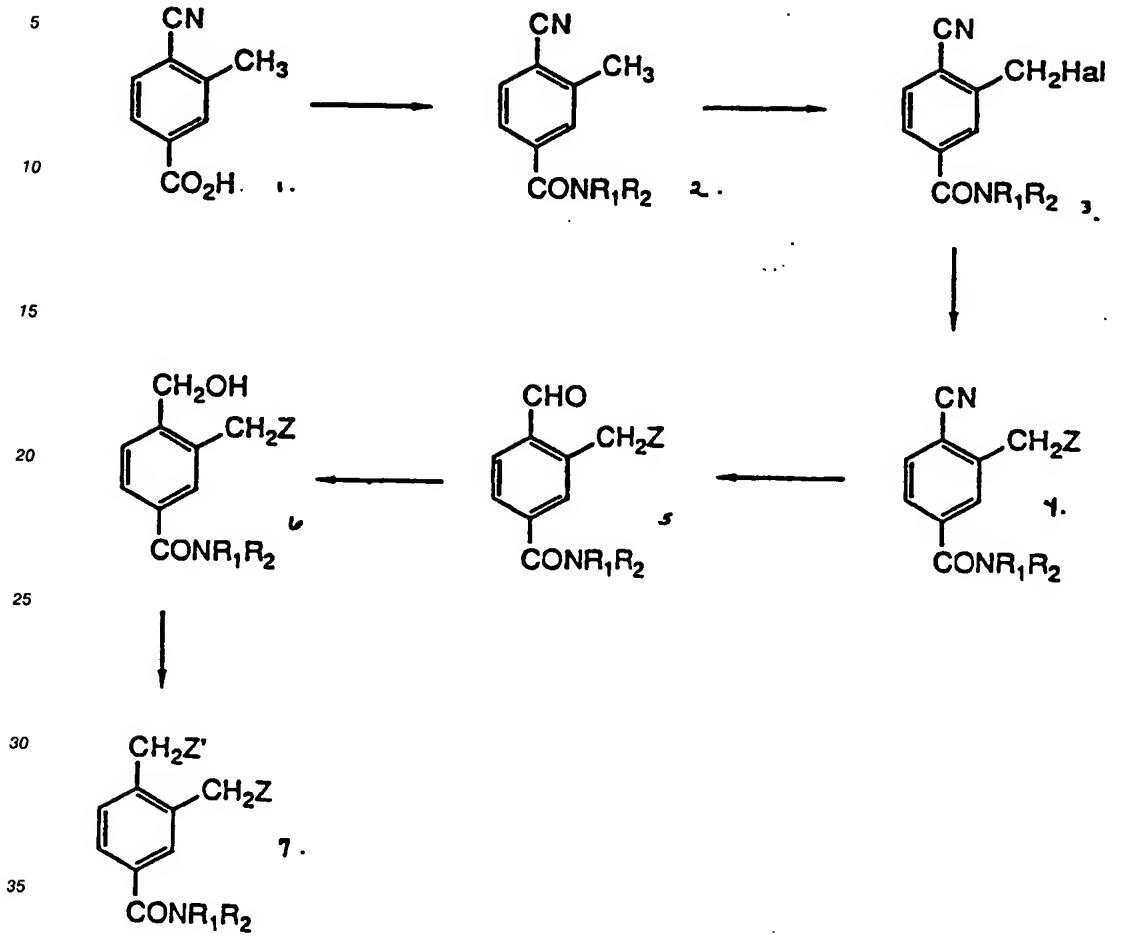
The above compound is prepared from 2,6-dimethoxy-4-methyl benzoic acid described by I. W. Mathison, R. C. Gueldner, D. M. Carroll, J. Pharma Sci 57 1820, (1968). The substituted benzoic acid is converted to the corresponding amide by first converting said compound to the acid chloride (using thionyl chloride) followed by condensation with N-cyclohexyl,N-cyclopentylamine. Irradiation of 2,6-dimethoxy-4-methyl-benz(N-cyclohexyl, N-cyclopentyl)amide following the procedure described for the preparation 2-methoxy-4-bromomethyl-5-bromobenz(N-cyclopentyl,N-2methylcyclohexyl)amide gives two products, 2,6-dimethoxy-3-bromo-4-methylbenz-(N-cyclohexyl, N-cyclopentyl)amide and 2,6-dimethoxy-3-bromo-4-bromomethylbenz(N-cyclohexyl,N-cyclopentyl)amide.

Scheme E



The imidazo[4,5-c]pyridine wherein R_3 is 4-chloro is prepared according to Scheme E starting with the imidazopyridine of Formula II. Position 1 of this compound is protected by reaction with a 2-(trialklysily) ethoxy methyl chloride and a base such as sodium hydride or potassium hydride in a polar aprotic solvent such as dimethylformamide. The reaction is carried out at room temperature. The protected imidazopyridine is reacted with m-chloroperbenzoic acid in methylene chloride at room temperature to give the pridine N-oxide product. The N-oxide product is heated in $POCl_3$ at 90°C to give 4-chloro-1-chloromethyl imidazopyridine. Treatment of this compound with sodium methoxide in methanol gave the 4-chloro-1-methoxy ethyl imidazopyridine. Reacting this compound with water/acid with heating gave the 4-chloro-imidazo[4,5-c] pyridine.

Preparation of Alkoxyalkyls



wherein R_1 and R_2 are defined as before; "Hal" is halogen; Z is alkoxy, thioalkyl, mercapto, hydroxy, halo, amino, alkyl and dialkylamino; and Z' chloro, bromo, methanesulfonyloxy or p-toluenesulfonyloxy.

When Y is substituted with alkoxyalkyl, such substitution may be carried out by methods known to those skilled in the art. Such a method might, for example, employ the substituted benzoic acid 1 (F. Fichter, G. Shetty, Helv. Chim. Acts, 20, 563 (1937)) as starting material. This is converted to the amide 2 by first converting acid 1 to the acid chloride by contact with agents such as oxalyl chloride or thionyl chloride and then treating the acid chloride with the desired amine. Amide 2 is converted to halide 3 by treatment with a halogenating agent such as N-bromosuccinimide. Halide 3 is versatile and in addition to serving as an intermediate to alkoxyalkyl compounds, is also an intermediate to alkylthioalkyl, hydroxyalkyl, mercaptoalkyl and alkylaminoalkyl compounds by treatment with the appropriate Z derivative. When halogen is displaced with a metal alkoxide, such as sodium methoxide, the methoxymethyl derivative (4, Z = OMe) is obtained. Conversion of 4 (Z = OMe) to aldehyde 5 (Z = OMe) is effected by controlled reduction with a reducing agent such as diisobutylaluminum hydride, followed by acid hydrolysis. Reduction of aldehyde 5 to alcohol 6 is effected by a second reduction with another reducing agent such as sodium borohydride or lithium tri-t-butoxyaluminum hydride. Alcohol 6 is converted to a derivative suitable for nucleophilic displacement such as 7 where Z' is a leaving group such as halide or aryl or alkyl sulfonate. Such conversion is effected by treatment of 6 with, for example, p-toluenesulfonyl chloride, methanesulfonyl chloride, or thionyl chloride.

Compounds where Y of formula I is substituted with hydroxy can be made from the corresponding methoxy substituted compounds by treatment with a demethylating reagent such as lithium ethyl mercaptide in a dipolar, aprotic solvent such as dimethylformamide at temperatures ranging from room temperature to 200°.

This invention also relates to a method of treatment for patients (or mammalian animals raised in the dairy, meat, or fur industries or as pets) suffering from disorders or diseases which can be attributed to PAF as previously described, and more specifically, a method of treatment involving the administration of compound (I) as the active ingredient.

Accordingly, compound (I) can be used among other things to reduce inflammation, to correct respiratory, cardiovascular, and intravascular alterations or disorders, and to regulate the activation or coagulation of platelets, the pathogenesis of immune complex depositions and smooth muscle contractions.

For the treatment of inflammation, cardiovascular disorder, asthma, or other diseases mediated by PAF, compound (I) may be administered orally, topically, parenterally, or by inhalation spray or rectally in dosage unit formulations containing conventional non-toxic pharmaceutically acceptable carriers, adjuvants and vehicles. The term parenteral as used herein includes subcutaneous injections, intravenous, intramuscular, intrasternal injection or infusion techniques.

The compounds of the present invention may be administered by any suitable route, preferably in the form of a pharmaceutical composition adapted to such a route, and in a dose effective for the treatment intended. Therapeutically effective doses of the compounds of the present invention required to prevent or arrest the progress of the medical condition are readily ascertained by one of ordinary skill in the art.

Accordingly, the invention provides a class of novel pharmaceutical compositions comprising one or more compounds of the present invention in association with one or more non-toxic, pharmaceutically acceptable carriers and/or diluents and/or adjuvants (collectively referred to herein as "carrier" materials) and if desired other active ingredients. The compounds and composition may for example be administered intravascularly, intraperitoneally, subcutaneously, intramuscularly or topically.

For oral administration, the pharmaceutical composition may be in the form of, for example, a tablet, capsule, suspension or liquid. The pharmaceutical composition is preferably made in the form of a dosage unit contained in a particular amount of the active ingredient. Examples of such dosage units are tablets or capsules. These may with advantage contain an amount of active ingredient from about 1 to 250 mg preferably from about 25 to 150 mg. A suitable daily dose for a mammal may vary widely depending on the condition of the patient and other factors. However, a dose of from about 0.1 to 3000 mg/kg body weight, particularly from about 1 to 100 mg/kg body weight may be appropriate.

The active ingredient may also be administered by injection as a composition wherein, for example, saline, dextrose or water may be used as a suitable carrier. A suitable daily dose is form about 0.1 to 100 mg/kg body weight injected per day in multiple doses depending on the disease being treated. A preferred daily dose would be from about 1 to 30 mg/kg body weight.

The dosage regimen for treating an infectious disease condition with the compounds and/or compositions of this invention is selected in accordance with a variety of factors, including the type, age, weight, sex and medical condition of the patient; the severity of the infection; the route of administration; and the particular compound employed and thus may vary widely.

For therapeutic purposes, the compound of this invention are ordinarily combined with one or more adjuvants appropriate to the indicated route of administration. If per os , the compounds may be admixed with lactose, sucrose, starch powder, cellulose esters of alkanoic acids, cellulose alkyl esters, talc, stearic acid, magnesium stearate, magnesium oxide, sodium and calcium salts of phosphoric and sulphuric acids, gelatin, acacia, sodium alginate, polyvinylpyrrolidone, and/or polyvinyl alcohol, and thus tableted or encapsulated for convenient administration. Alternatively, the compounds may be dissolved in water, polyethylene glycol, propylene glycol, ethanol, corn oil, cottonseed oil, peanut oil, sesame oil, benzyl alcohol, sodium chloride, and/or various buffers. Other adjuvants and modes of administration are well and widely known in the pharmaceutical art. Appropriate dosages, in any given instance, of course depend upon the nature and severity of the condition treated, the route of administration, and the species of mammal involved, including its size and any individual idiosyncrasies.

Representative carriers, diluents and adjuvants include for example, water, lactose, gelatin, starches, magnesium stearate, talc, vegetable oils, gums, polyalkylene glycols and petroleum jelly. The pharmaceutical compositions may be made up in a solid form such as granules, powders or suppositories or in a liquid form such as solutions, suspensions or emulsions. The pharmaceutical compositions may be subjected to conventional pharmaceutical operations such as sterilization and/or may contain conventional pharmaceutical adjuvants such as preservatives, stabilizers, wetting agents, emulsifiers and buffers.

Dosage levels of the order from about 1 mg to about 100 mg per kilogram of body weight per day are useful in the treatment of the above-indicated conditions (from about 50 mg to about 5 gs. per patient per day). For example, inflammation is effectively treated and anti-pyretic and analgesic activity manifested by the administration from about 25 to about 75 mg of the compound per kilogram of body weight per day (about 75 mg to about 3.75 gm per patient per day). Preferably, from about 5 mg to about 50 mg per kilogram of body weight per daily dosage produces highly effective results (about 250 mg to about 2.5 gm per patient per day).

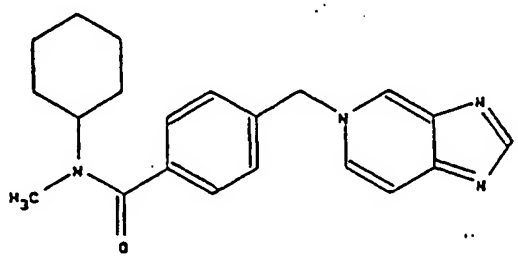
The amount of active ingredient that may be combined with the carrier materials to produce a single dosage form will vary depending upon the host treated and the particular mode of administration. For example, a formulation intended for the oral administration of humans may contain from 5 mg to 95 mg of active agent compounded with an appropriate and convenient amount of carrier material which may vary from about 5 to 95 percent of the total composition. Dosage unit forms will generally contain between from about 25 mg to about 500 mg of active ingredient.

It will be understood, however, that the specific dose level for any particular patient will depend upon a variety of factors including the activity of the specific compound employed, the age, body weight, general health, sex, diet, time of administration, route of administration, rate of excretion, drug combination and the severity of the particular disease undergoing therapy.

The following Examples are to further illustrate the present invention. In the Examples, all parts are parts by weight unless otherwise expressly set forth.

EXAMPLE 1 (= example 13)

5-[4-(N-methyl-N-cyclohexylcarboxamido)benzyl]imidazo[4,5-c]pyridine



To a stirred solution of imidazopyridine (5.86 g, 49.2 mmol) in DMF (125 ml) under a nitrogen atmosphere was added washed, dried sodium hydride (prepared from 3.54 g of 50% dispersion in oil by washing four times with 50-75 ml portions of hexane). After stirring for 1 hr at room temperature, the evolution of hydrogen gas had ceased and the reaction was cooled to -10 °C.

DMF was removed in vacuo and the residue was diluted with H_2O (200 ml) and the resulting solution was saturated with sodium chloride. The aqueous solution was extracted four times with ethyl acetate (100 ml portions) and the combined organic layers were washed three times with saturated aqueous sodium chloride solution (150 ml portions). After drying over sodium sulfate, the organic solution was filtered and concentrated in vacuo to give 13.38 g of crude product as a brown gum. This material was chromatographed on silica gel using ethanol/chloroform/ammonium hydroxide (20/79/1) to give 3.13 g of compound as an orange oil that crystallized on treatment with ethyl acetate. Recrystallization from ethyl acetate yielded 1.06 g.

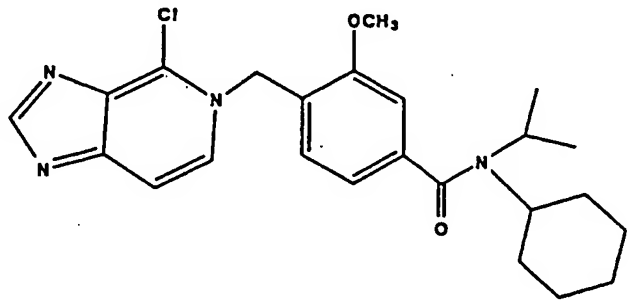
Preparation of 5-[4-{(N-cyclohexyl,N-isopropyl)carboxamido}-2-methoxybenzyl]-4-chloro-imidazo[4,5-c]-pyridine



Preparation of the 4-chloro-imidazo [4,5-c]pyridine starting material as well as the 3-methoxy-4-bromomethyl-(N-cyclohexyl,N-isopropyl)benzamide have been described earlier in this specification. Coupling of the 4-chloro-imidazo[4,5-c]pyridine to the 3-methoxy-4-bromomethyl-(N-cyclohexyl,N-isopropyl)-benzamide in dimethylacetamide at 85-90 ° for 26h gives the titled compound.

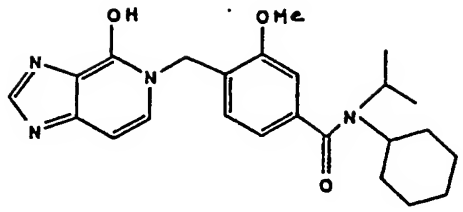
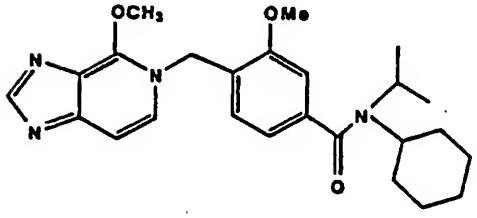
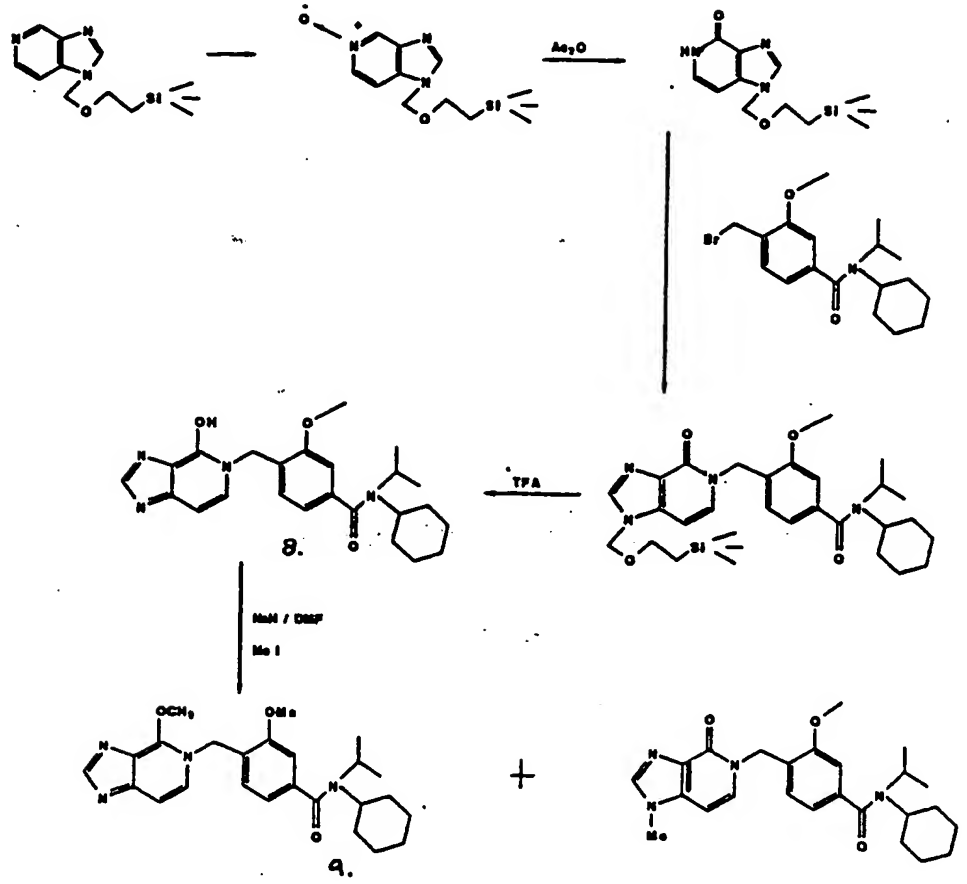
Preparation of



and



The above compounds can be synthesized according to the following scheme -



The N-1 compound of imidazopyridine is protected by SEM-C1 and converted to a pyridine N-oxide using m-chloroperbenzoic acid in a manner described for the preparation of 4-chloro-imidazo[4,5-c]pyridine. The pyridine-N-oxide compound is refluxed in acetic anhydride for 4 hrs. to give 4-oxo-1-(2-trimethylsilyl)-ethoxymethyl-imidazo[4,5-c]pyridine. Reacting this compound with 4-bromomethyl-3-methoxy-benz-[N-isopropyl,N-cyclohexyl) amide in dimethylformamide and sodium hydride at room temperature for 4 hours gives the 5-benzylated product. Clevage of the SEM-group is accomplished by trifluoroacetic acid at 50 • C for 18 hours to give the compound of formula 8 (titled compound). Treatment of the 4-hydroxy group of the compound of formula 8 with sodium hydride/iodomethane gives the compound of formula 9 (titled compound).

EXAMPLE 65

PAF-induced platelet aggregation and secretion: Washed, [^{3}H]serotonin-labeled rabbit platelets were prepared as previously described in COX, C. P., J. LINDEN and S. I. SAID: VIP elevates platelet cyclic AMP (cAMP) levels and inhibits in vitro platelet activation induced by platelet-activatinq factor (PAF). Peptides 5: 25-28, 1984, and maintained in an atmosphere of 5% CO_2 at 37 • C until used in the bioassay. Aliquots of platelets (2.5 x 10^8/ml) were incubated with either an antagonist of PAF or the appropriate vehicle for 60 sec prior to the addition of PAF (0.2 nM to 0.2 µM). Aggregation was continuously monitored on a strip-chart recorder and recorded as the height of the tracing at 60 sec after the the addition of PAF. Secretion of [^{3}H] serotonin was measured in a sample of the platelet suspension removed at 60 sec after the addition of PAF. The percent inhibition of aggregation and secretion was calculated by comparing antagonist-treated platelets with the appropriate vehicle-treated control platelets. Each combination of antagonist and PAF was

repeated 12-15 times, using several different platelet preparations. IC_{50} values were determined by inspection of the dose-response curves.

EXAMPLE 66

Inhibition of ^{3}H-PAF Binding to Human Platelet Membrane Receptors

Receptor Preparation: Ten units of in-dated human packed platelets, each containing 45-65 ml platelet rich-plasma, were purchased from a commercial blood bank. Disposable plasticware was used throughout for receptor preparation. The units were pooled and a 1 ml aliquot was removed for determination of platelet concentration, using a Coulter Counter. The remaining platelet rich plasma was dispensed into 50 ml conical tubes and centrifuged at room temperature for 15 minutes at 3000 RPM (2300 x g). Plasma was decanted and the platelets were resuspended in 35 ml of buffer (10 mM Trizma 7.0, 2 mM EDTA (dipotassium salt), and 150 mM KCl) and transferred to fresh tubes, which were centrifuged again as above. The platelets were washed 3 times, avoiding contaminating erythrocytes at the bottom of the pellets. Pellets were consolidated at each step, and by the last wash with EDTA/KCl buffer, most of the erythrocytes were in 1 tube. The pellets were resuspended in buffer containing 10 mM Trizma 7.0 with 10 mM $CaCl_2$. Following centrifugation, the buffer was decanted and the pellets were resuspended in the $CaCl_2$ buffer, avoiding erythrocyte contamination by recovering less than 100% of the platelet pellets. The resuspended platelets were dispensed in 8-10 ml aliquots into Corex® tubes and disrupted by three cycles of freezing (dry ice/ethanol) and thawing (24 °C). The tubes were centrifuged at 40,000 x g for 20 minutes at 4 °C. Supernatants were decanted and each pellet was resuspended in 5-7 ml 10 mM Trizma 7.0. All resuspended pellets were pooled and aliquots of about 1200 µl were dispensed into 1.5 ml microfuge tubes and frozen at -70 °C. Protein content was determined by a fluorescamine protein assay.

Assay Methods: Receptor Characterization - Each receptor preparation was evaluated to determine the number of receptor populations, the number of PAF receptor equivalents/mg protein and the dissociation constant (K_D) for PAF binding. This required 2-3 experiments in which the protein concentration was held constant and the ^{3}H-PAF ligand concentration was varied from approximately 0.10-2.5 nM and the data was analyzed by Scatchard methodology. Total incubation volume was 250 µl for these procedures and incubations were conducted at 24 °C for 30 minutes. For further experimentation, total incubation volumes are 500 µl. Protein and ligand concentrations were adjusted to give 0.075 nM receptor equivalents in the presence of 0.75 nM ^{3}H-PAF. Each receptor preparation was then used to determine the dose - response displacement relationship of unlabeled PAF and the PAF antagonist, triazolam. As long as the K_D value and IC_{50} values for PAF and triazolam were consistent with similar data collected from past receptor preparations used in the assay, the new receptor preparation was used for evaluating compounds.

Assay Methods: Routine Assay of Compounds - The compounds were weighed precisely and solubilized in quantities of DMSO such that a 5 µl aliquot in the incubate would deliver the desired compound concentration. Compounds tested for the first time in this assay were evaluated at a concentration of 50 µM in the incubation medium. All compounds were generally solubilized in DMSO for about 2 hours prior to assay. Triazolam was always included in each screening assay as a compound inhibition control. A standard concentration of 50 µM inhibited ^{3}H-PAF binding by approximately 50%. Nonspecific binding control solution was made by drying to completion about 26.2 µl unlabeled PAF under a stream of argon. PAF was resolubilized in 1000 µl DMSO. When delivered in a 5 µl aliquot, the final concentration of 1 µM PAF in the incubate exceeded by 1000-fold the concentration of ^{3}H-PAF.

All buffers containing proteins were made at room temperature on the day of assay. Assay buffer was prepared by adding 125 mg human albumin to 25 ml of stock buffer (10 mM Trizma 7.4 with 20 mM $CaCl_2$). Rinse buffer was made by adding 20 grams bovine serum albumin to 1000 ml stock buffer. About 80 ml of rinse buffer was decanted into a small pyrex® dish and used to soak 65 Whatman GF/C® 2.5 cm glass filters. The remaining rinse buffer was poured into a repipet and placed into an ice bath along with the filters.

Ligand for assay was prepared by adding about 10 µl of stock ^{3}H-PAF (DuPont NEN, NET-668) to 14 ml of assay buffer. Since the amount of ^{3}H-PAF in the final incubate was to be 0.75 nM, the actual amount of stock ^{3}H-PAF to be used had to be determined for each lot of material based upon its specific activity.

Membrane receptors for assay were prepared by thawing the appropriate number of tubes at room temperature and adding membranes to 10 mM Trizma 7.0 containing 10 mM $CaCl_2$. A total volume of 14 ml was made. The actual amount of membranes needed was determined by the requirement to have 0.075 nM PAF receptor equivalents per assay tube. All materials were kept in motion by rocking on a rocker plate.

First, 5 µl of compound or DMSO was added to each 12 X 75 mm polypropylene tube, followed by the addition of 95 µl assay buffer. Next, 200 µl ^{3}H-PAF was added to each tube and 3 aliquots of ^{3}H-PAF taken at different times during the dispensing were placed in scintillation vials. The reaction was initiated by the addition of 200 µl of membranes. All tubes were very briefly vortexed and placed in a 24°C water bath for about 30 minutes. During this time, Whatman GF/C® filters were placed on the filter racks of 5 Millipore® vacuum manifolds. The incubations were terminated by first adding 4 ml ice-cold rinse buffer to each incubation tube and then decanting them over the filters under vacuum. Tubes and filters were rinsed twice more. Each filter was placed into a 20 ml scintillation vial to which 20 ml Aquasol® (DuPont NEN, NDF 952) was added. All vials were given 2 hours in the dark for photo and chemiluminence to dissipate prior to liquid scintillation counting.

In summary, each incubation tube contained 500 µl total volume of incubate. This consisted of 5 µl drug with DMSO or only DMSO, 95 µl assay buffer, 200 µl ^{3}H-PAF (0.75 nM final concentration) and 200 microleters membrane receptors (0.075 nM final concentration). 60 tubes per assay were run and each dose was performed in triplicate. Controls in every assay consisted of 2 diluent (DMSO) "0" controls (2 triplicate determinations placed at different positions within the 60 tube assay), 1 nonspecific binding control, and 1 triazolam drug control. The 16 remaining doses were used to test 16 different compounds at the screening dose of 50 µM, or to run dose-response determinations for a compound. In general, dose-response curves were composed of 4 compound doses designed to inhibit ^{3}H-PAF binding by 15-85%, with at least 1 dose on each side of the 50% point.

Routine Assay Calculations: Triplicate DPM determinations (corrected for background) within a single compound dose were averaged while all 6 determinations of total binding ("0" dose, DMSO only) were averaged. The amount for nonspecific binding (1 µM PAF) was subtracted from all the dose averages, giving an amount of specific binding in all cases. The percent displacement of ^{3}H-PAF or inhibition of binding was calculated by the formula STBo-SBc/STBo x 100, where STBo = specific binding of "0" dose controls and SBC = specific binding in the presence of compound. If a compound tested at the initial screening dose of 50 µM inhibited binding by 45% or more, the compound was considered active and was tested in a dose-response manner to determine an IC_{50} value.

Compounds inhibiting PAF binding by less than 45% at a 50 µM concentration were considered inactive and no further testing was done.

IC_{50} values were determined on active compounds in subsequent tests. Three or more compound doses must inhibit ^{3}H-PAF binding between 15-85%. Using a computer program, % displacement data was transformed (logit) and a least squares linear regression was performed on the data meeting the 15-85% requirement to determine IC_{50} values from data points derived from the same assay.
